ſ

We call a pop action Z > (X, 1) Multiple Recurrence action (MR) if the (MR) property above helds for it. We already "saw" that weakly mixing and soupced actions are (MR). The way Furstenberg proves (MR) for all actions is by showing that every action is "built" out of weakly wixing al compact retion. This "built" is by extensions.

Def. For any semigroup action I M (X, M), another atom F'(Y, v) is called a factor of d lor d is called the extension of B) if there is a the how our orphism/ factor map T: X >> Y, E.R. 7 mensurable TT: X >> Y that preserve the newsure, i.e. It y = v (hence puto a.e.), I T is equivariant, i.e. VOEL, TTO Y = Jo IT a.e.

Example. Products: let Pred (x, r) I Prop (Y, v), Ken take the product action TNXXP (XXY, JXX) by  $\gamma.(x,y) := (\vartheta_{2x}, \vartheta_{y})$  let  $\pi: X \times Y \to X$ Y Tis be the X-projection. Then It is shis a factor map. Tix x Tix Bat X

A tautor I (Y, v) of I (K, r) can be identified ville a T-invariant sub-5-algebra of BCX), namely= By := TIT B(Y), This By is the o-algebra of Bonel IT-invariant suby (for products, it's Borel ut the are unides of "columns"). Conversely, it C = D(X) is a P-inversion sub-o-algebra, then I Fondor map IT: X -> (211) with some nemme  $\mathcal{V}$  on  $(2^{(N)})^{r}$  i.t.  $\mathcal{C} = \Pi^{-1} \mathcal{B}((2^{(N)})^{r})$ , They invariant sub-o-algebras are called factor sub-oalgebras or just Embors.

let 2 (x, x) I let Z ~ (Y, v) be a factor, corresponding to sub-o-algebra By. To define that it nears for this extension to be nearly mixing or compact, we look at each preimage"s of an S-orbit (y), al say that the restriction of I on Xy is neakly mixing or ungact, but we want to do so multorady. Since both which are defined using inver product, we relativize the notion of inter product to By as follows: & f, y & L'(x, M) < f, g > = E, (fg | By) it's a function. Nonchittonal expectation

 $p_{i} \in L^{2}(X|Y) := \frac{1}{4} \int e^{2}(X,Y) = \|f\|_{2}^{2} e^{2}(\mu, r) \int e^{2}(\mu, r) \int$ Now we can define weakly mixing I compart for, this new Hilbert module over L<sup>o</sup>(X, h).

Def. The extension  $X \rightarrow 1$  is weakly mixing if  $\forall 1_{y} \in L^{2}(X|Y)$  with  $\mathbb{E}(F \mid \mathcal{B}_{Y}) \equiv 0 \equiv \mathbb{E}(g \mid \mathcal{B}_{Y})$ ,  $\lim_{N \to \infty} \frac{1}{N+1} \sum_{\mu=0}^{\infty} \langle T^{\mu} f, g \rangle_{Y} = 0 \quad \text{in $L^{-norm}$.}$ 

It's harder to define corporet codensions at we'll skip it. What Furstenberg really proved is the following:

Theorem let X -> Y be an extension of pup 2-actions. (a) If Y is (MR) I this extension is either weakly mixing or compart, then X too is (MR). (5) Dicholony: If this extension is not nearly mixing then I nontrivial X >> Y<sup>t</sup> >> Y 4.t. Y<sup>t</sup> >> Y is wapact.

Thus, if by Zora's lemma, we take a maximal (MR)

for tor Y of X then Y would have to be equal to X hence othernise, either X > Y neckly mixing or I x > Yt > Y with Yt > Y with of either case contracticty the maximality of Y by (a). Mi, "proves" Forstenberg MR Reorem. And the sequence (ordinal-length) one yets instead of Zorn:  $\chi_{:=} [\cdot] \leftarrow \chi_{1} \leftarrow \chi_{2} \leftarrow \dots \leftarrow \chi_{\omega} \leftarrow \chi_{\omega_{t/}} \leftarrow \chi_{o_{t/2}} \leftarrow 00$ one (X, = X. This is called a Furstanberg tour.
